1 Background

The goal of "*Carbon Neutrality*" is gaining increasing momentum in the European political arena amid substantial indicators of an incoming climate change which might have deleterious effects at the societal, economic and, most importantly, environmental level. Household energy consumption plays a pivotal role in overall social sustainability since it accounts for a substantial share of the total energy demand in most developed countries. Within this sector, electricity consumption provides a useful proxy for household energy demand and can be put into relationship to structural characteristics of the buildings as well as the socio-economic profile of their occupants.

Dwelling-related attributes such as floor area, dwelling type, construction period, and Energy Performance Certificate (EPC) labels are consistently identified as important predictors of electricity demand (McLoughlin et al., 2013; Santin et al., 2009). Intuitively, larger dwellings typically require more energy for lighting, heating, cooling, and appliance use, while older buildings are constructed with materials which provides poorer insulation and therefore larger heat dissipation. Nevertheless, these variables interacts with socio-economic factors. Larger households topically host a higher number of occupants, therefore they can share the consumption for heating, refrigerators and air conditioning lowering the per-capita consumption. Similarly, high EPC label buildings are prerogative of high-income classes which might use a larger number of appliances and indulge into energy-consuming behaviours going to erode the benefits of a properly insulated house in terms of energy savings (Aydin et al., 2017).

Using household electricity consumption as a proxy for energy demand, this cross-sectional study examines its relationship with building characteristics (e.g. floor area, EPC label, construction era) and socio-economic factors (number of permanent residents and annual net household income) collecting data from 2500 households in Belgium. Importantly, the study aims at characterising the interplay between EPC labels and the other factors involved in energy consumptions to provide data-driven tools to decision-makers.

2 Data management

2.1 Data Cleaning

After loading the data, three observations (rows 66, 36, and 135) were removed from the dataset according to the instructions. Subsequently, the dataset was cleaned by excluding observations with missing values in the variables EPC label (`epc_label`) and annual household electricity consumption (`annual_kwh`) (none of the variables displayed missingness above 5%). This step ensures that the analysis is conducted only on complete cases for the key variables of interest. Missing values in other variables were retained (see appendix) without imputation. To inspect the distribution of electricity consumption and identify potential extreme values, the observations were sorted in decreasing order of annual electricity consumption (`annual_kwh`). Five observations (row 267, 1330, 1570, 369, 12) were two orders of magnitude larger than the others (172 to 312 times larger) and, therefore, were removed as were attributed to imputation error.

2.2 Data Coding

Variables were coded according to their type: continuous (e.g., `annual_kwh`, `sq_meters`, `income_euro`), count (`occupancy_count`), ordinal (`epc_label`, `building_era`), categorical (`roof_color`), or binary (`pet_ownership`). Table 1 summarizes their descriptions and coding schemes.

Table 1: Data Dictionary

Name	Description	Type_Coding
annual_kwh	yearly electricity use	Continuous (kWh/year)
sq_meters	indoor living area	Continuous (m^2)
epc_label	energy performance certificate	Ordinal: A, B, ..., F
building_era	construction period	Ordinal: dummy coded; ref = Pre-1970
income_euro	net household income	Continuous (€/year)
occupancy_count	permanent residents	Count: 1, 2, ..., n
dist_to_brussels	distance to Brussels center	Continuous (km)
roof_color	roof tile color	Categorical: e.g., red, black, other
pet_ownership	owner has a pet	Binary: 0 = No, 1 = Yes

3 Descriptive Statistics

3.1 Categorical variables

The distribution of EPC labels is relatively balanced across categories. Labels A (22.2%) and C (21.3%) are the most common, followed by B (17.6%) and D (15.7%). Lower-efficiency categories E occur less frequently, 13.6% and F 9.6% respectively. Buildings constructed between 1970 and 2000 represent 34.4% of the sample, pre-1970 buildings account for 33.1%, and post-2000 buildings make up 32.6%. Occupancy count goes from 1 to 7 with all counts accounting approximately 14-15%. Red roofs are the most common (35.2%), followed closely by black roofs (33.3%) and other colors (31.5%). Almost one in four (39.6%) owners has a pet, while 60.4% does not. None of the categories appear too sparse, suggesting that all variables can be retained for modelling without concerns about low cell counts. Overall, the categorical variables show meaningful variation across categories. EPC labels are generally balanced across the different categories, indicating that extremely efficient or inefficient homes are not rare in this data. Building era and roof color are also evenly distributed while pet ownership is generally more common.

Edo's comment: i think the sentence below can be replaced by the actual description as in the paragraph above and tables will go in the appendix These summary tables should help show if the EPC labels are balanced or skewed, if the building eras arw clustered within one period, if the roof colours or pet ownership categories have enough variation to be meaningful predictors. We can also sue them to investigate whether any category has very low counts, which can affect model stability.

3.1.1 Summary tables

Table 2: EPC Label Distribution

epc_label	n	percent
A	552	22.2
B	436	17.6
C	529	21.3
D	389	15.7
E	337	13.6
F	239	9.6

Table 3: Building Era Distribution

building_era	n	percent
1970-2000	853	34.4
Post-2000	808	32.6
Pre-1970	821	33.1

Table 4: Roof Color Distribution

roof_color	n	percent
Black	826	33.3
Other	783	31.5
Red	873	35.2

Table 5: Pet Ownership Distribution

pet_ownership	n	percent
0	1500	60.4
1	982	39.6

Table 6: Occupancy Count Distribution

occupancy_count	n	percent
1	350	14.1
2	354	14.3
3	342	13.8
4	376	15.1
5	375	15.1
6	341	13.7
7	339	13.7

NA	5	0.2
